

Do it for me

Do it for me : An AI-Powered Automated Job Discovery and Application Platform

Introduction

Searching for jobs has become increasingly time-consuming. Job seekers often spend hours monitoring multiple Telegram channels, reading lengthy job descriptions, comparing opportunities with their qualifications, and preparing personalized application emails

To address this challenge, this project proposes Do it for me , an AI-powered job automation platform that continuously monitors Telegram job channels, intelligently evaluates job opportunities based on a user's profile, and assists—or fully automates—the application process.

Problem Statement

Many organizations and recruiters use Telegram to advertise vacancies because of its speed and wide reach. However, job seekers must manually monitor multiple channels, filter irrelevant posts, compare requirements with their own skills, and write customized application emails for each opportunity. This repetitive process is inefficient and often results in missed deadlines or overlooked opportunities.

Project Objectives

The primary objective of Do it for me is to develop an intelligent platform that automates the entire job discovery process. Specifically, the system will:

- Continuously monitor selected Telegram channels for new job postings.
- Detect and extract relevant job information automatically.
- Analyze each job against the user's skills, experience, and preferences using Artificial Intelligence.
- Recommend only the most suitable opportunities.
- Generate personalized cover letters and professional application emails.
- Allow users to manually review applications or automatically submit them based on configurable preferences.
- Provide a modern dashboard for tracking applications, statistics, and system activity.

Proposed Solution

Do it for me combines real-time messaging technology, artificial intelligence, and workflow automation into a single platform. Instead of requiring users to constantly monitor Telegram channels, the system performs this task automatically.

Whenever a new message appears in a monitored channel, JobBot determines whether it represents a genuine job opportunity. If it does, the system extracts important

details such as the company name, job title, required skills, application deadline, contact information, and work location.

The extracted information is then analyzed using Google's Gemini AI, which compares the job requirements with the user's profile and calculates a compatibility score. Based on this analysis, the system recommends whether the user should apply, consider the opportunity, or skip it altogether.

For highly compatible jobs, Do it for me can automatically generate a professional, personalized cover letter tailored to the specific position. Depending on the user's preferences, the application can either be saved as a draft for review or sent directly to the employer through email using a configured SMTP service.

Throughout this process, the user can monitor application history, AI recommendations, and overall performance through an intuitive web dashboard.

System Architecture

The project follows a modern client-server architecture consisting of four primary components:

Backend

The backend serves as the core automation engine responsible for user authentication, Telegram monitoring, AI integration, business logic, database management, and email processing. It is developed using **Laravel**, a robust PHP

framework that provides a clean MVC architecture, secure authentication, and powerful API development capabilities. **PostgreSQL** is used as the primary database, with **Laravel Eloquent ORM** managing data models and database interactions efficiently. Laravel's built-in queue system is used to handle background tasks such as AI processing, Telegram monitoring, and email dispatch, ensuring the application remains responsive and scalable.

Telegram Integration

Using **GramJS**, the system connects directly to Telegram through the MTProto protocol, enabling real-time monitoring of selected channels without relying on bots or manual intervention.

Artificial Intelligence

Google **Gemini AI** powers the intelligent analysis engine. It evaluates job suitability, provides detailed recommendations, and generates customized cover letters and application emails.

Frontend

The user interface is developed using **Vue 3**, **Vite**, **Tailwind CSS**, **Pinia**, and **Chart.js**, providing users with a responsive dashboard for managing profiles, monitoring applications, adjusting automation settings, and viewing statistics.

Expected Outcomes

Upon completion, JobBot will provide users with a reliable and intelligent job-search assistant capable of:

- Monitoring Telegram job channels automatically.
- Detecting and organizing job opportunities in real time.
- Evaluating job suitability using AI.
- Generating personalized application emails.
- Supporting both manual and automatic job applications.
- Providing insightful dashboards and application analytics.
- Reducing the overall time required to search and apply for jobs.

Benefits

The proposed system offers several advantages:

- Saves significant time by automating repetitive job-search tasks.
- Increases the chances of discovering relevant job opportunities before deadlines.
- Produces professional, AI-generated application emails tailored to each employer.
- Eliminates the need to manually monitor numerous Telegram channels.
- Provides centralized management of applications, recommendations, and statistics.
- Offers flexibility by allowing users to choose between manual review and fully automated applications.

Conclusion

JobBot represents a practical application of artificial intelligence and automation in solving a common challenge faced by modern job seekers. By integrating Telegram monitoring, AI-powered job matching, automated email

generation, and a user-friendly management dashboard, the system transforms the traditional job search into an efficient, intelligent, and largely automated process.

The project demonstrates how emerging technologies can be combined to create a real-world solution that improves productivity, reduces manual effort, and helps users discover and apply for employment opportunities more effectively.
